

Table 1-37. Birth Probabilities by Parity, Exact Age of Woman, According to Race of Child, for Women in Each Cohort From 1946 to 1980:  
United States, 1995

(A cohort is identified by the year in which the women were born. Since these women retain this designation throughout their childbearing years, their fertility can be followed over time. Based on births adjusted for underregistration and numbers of women adjusted for underenumeration and misstatements of age in the censuses. Parity refers to the number of children born alive to a woman. Probabilities are the number of births per 1,000 women of specified parity and exact age. Figures in the "0 parity" column show the probability of first births to "0 parity" women, those in the "1 parity" column show the probability of second births to "1 parity" women, etc. For method of computation, see Technical Appendix. Probabilities are computed from central birth rates and parity distributions. Probabilities are ultimately based on central birth rates which are by race of child. The rates in this table are based on postcensal population estimates consistent with the 1990 census. These rates will be revised based on the results of the 2000 census when population data in the necessary detail become available)
